

# Tetraquark mixing framework for light mesons in the $0^+$ channel

Hungchong Kim (김흥종)  
Korea Aerospace U.

- We explore tetraquark possibility in the light meson system.
- In particular, we reexamine the **diquark-antidiquark** model by Jaffe and motivate **tetraquark mixing framework** for the resonances in the  $0^+$  channel.
- Basically we introduce **two types of tetraquark** and their strong **mixing** in order to explain **two nonets** in PDG.

A brief review on **diquark-antidiquark** model

- Well-known model for tetraquark by Jaffe (1977).
- Tetraquarks are constructed by combining diquark ( $qq$ ) and antidiquark ( $\bar{q}\bar{q}$ ),  $qq\bar{q}\bar{q}$ , ( $q = u, d, s$ ), while assuming all the quarks are in an  $S$ -wave.
- In this construction, the **spin-0 diquark** with  $qq \in J = 0, \bar{3}_c, \bar{3}_f$ , is used
  - because this is the **most compact object** among all possible diquarks.
  - So it can be used as a starting building block for tetraquarks.

$\langle qq \text{ structure [Jaffe, hep-ph/0001123]} \rangle$

Spin	Color	Flavor	$\langle V_{CS} \rangle$	Type
0	$\bar{3}_c$	$\bar{3}_f$	-8	Attractive
1	$6_c$	$\bar{3}_f$	-4/3	Attractive
1	$\bar{3}_c$	$6_f$	8/3	Repulsive
0	$6_c$	$6_f$	4	Repulsive

Possible diquarks allowed by Pauli principle.  
 $\langle V_{CS} \rangle$  is given in a certain unit.

Hyperfine color-spin interaction

$$V_{CS} \propto - \sum_{i \neq j} \lambda_i \cdot \lambda_j J_i \cdot J_j$$

$\lambda_i$ : Gell-Mann matrix for color  
 $J_i$ : spin,

$qq\bar{q}\bar{q}$  system

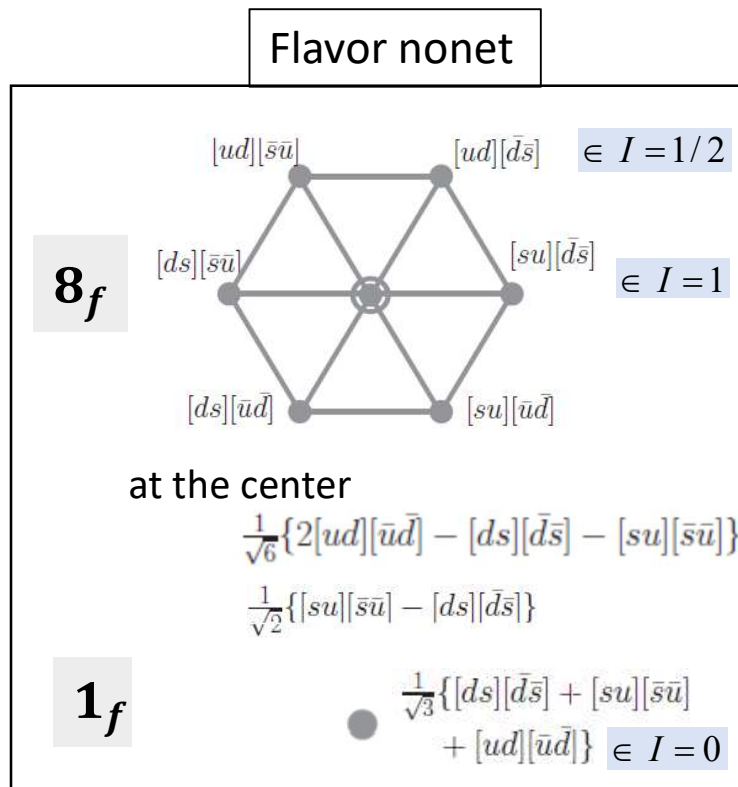

$qq\bar{q}\bar{q}$  from the spin-0 diquark

$$[qq \in (J = 0, \bar{3}_c, \bar{3}_f)] \otimes [\bar{q}\bar{q} \in (J = 0, 3_c, 3_f)]$$

Spin:  $[J_{12} = 0] \otimes [J_{34} = 0] = [J = 0] \Rightarrow |J, J_{12}, J_{34}\rangle = \underline{|000\rangle}$

Color:  $\bar{3}_c \otimes 3_c \Rightarrow 1_c$ , i.e.,  $|1_c, \bar{3}_c, 3_c\rangle$ ,  $\frac{1}{\sqrt{12}} \epsilon_{abd} \epsilon^{aef} (q^b q^d) (\bar{q}_e \bar{q}_f)$

Flavor: forming a nonet,  $\bar{3}_f \otimes 3_f = 8_f \oplus 1_f \Rightarrow |8_f, \bar{3}_f, 3_f\rangle \oplus |1_f, \bar{3}_f, 3_f\rangle$

Notation:  $[ud] = \frac{1}{\sqrt{2}}(ud - du)$ , etc.

Characteristics of Jaffe's tetraquarks

1. Spin and parity are  $J^P = 0^+$ .
  2. The  $I_z = 0$  members have  $C = +$ .
  3. Possible isospins are  $I = 0, \frac{1}{2}, 1$ .
  4. The mass ordering among the octet members,  $(I = 1) > (I = \frac{1}{2}) > (I = 0)$ ,  
ex)  $M([su][\bar{d}\bar{s}]) > M([su][\bar{u}\bar{d}])$ .
- ✳ Note, two-quark system ( $q\bar{q}$ ) has the opposite ordering.

Possible candidates must be sought from the resonances with  $J^{P(C)} = 0^{+(+)}$

Light nonet (Jaffe's selection)

Name	I	J <sup>PC</sup>	Mass(MeV)	Γ(MeV)
f <sub>0</sub> (500)	0	0 <sup>++</sup>	400-550	400-700
f <sub>0</sub> (980)	0	0 <sup>++</sup>	990	10-100
a <sub>0</sub> (980)	1	0 <sup>++</sup>	980	50-100
K <sub>0</sub> <sup>*</sup> (800)	1/2	0 <sup>+</sup>	682	547

The lowest-lying resonances in J<sup>P(C)</sup> = 0<sup>+(+)</sup>

Two states in  $I = 0$  may be a mixture of:  $f_0(500)$ ,  $f_0(980)$

- In PDG, the lowest-lying states in  $J^P = 0^+$ ,  $f_0(500)$ ,  $f_0(980)$ ,  $K_0^*(800)$ ,  $a_0(980)$ , seem to form a nonet ( $8_f \oplus 1_f$ )
  - A clue for the octet? Gell-Mann–Okubo mass relation works within ~14%,  $M^2[a_0(980)] + 3M^2[f_0(500)] \approx 4M^2[K_0^*(800)]$ .
- They satisfy the tetraquark characteristics above,
  - the anticipated isospins,  $I = 0, \frac{1}{2}, 1$ , and
  - the mass ordering,  $M[a_0(980)] > M[K_0^*(800)] > M[f_0(500)]$ .

Light nonet is the strong candidate for the tetraquark although their masses are rather small to be four-quark states.

Another tetraquark in  $0^+$  can be constructed by the spin-1 diquark

because this spin-1 diquark also forms a bound state even though it is less compact than the spin-0 diquark.

$\langle qq \text{ structure} \rangle$

Spin	Color	Flavor	$\langle V_{CS} \rangle$
0	$\bar{3}_c$	$\bar{3}_f$	-8
1	$6_c$	$\bar{3}_f$	-4/3
1	$\bar{3}_c$	$6_f$	8/3
0	$6_c$	$6_f$	4

$qq\bar{q}\bar{q}$  from the spin-1 diquark in  $J^P = 0^+$  channel

Spin:  $[J_{12} = 1] \otimes [J_{34} = 1] \Rightarrow [J = 0] \Rightarrow |J, J_{12}, J_{34}\rangle = |011\rangle$

Color:  $6_c \otimes \bar{6}_c \Rightarrow 1_c$ , i.e.,  $|1_c, 6_c, \bar{6}_c\rangle$ ,  $\frac{1}{\sqrt{96}}(q^a q^b + q^b q^a)(\bar{q}_a \bar{q}_b + \bar{q}_b \bar{q}_a)$

Flavor:  $\bar{3}_f \otimes 3_f = 8_f \oplus 1_f$  also form a nonet in flavor !

$\Rightarrow$  This 2<sup>nd</sup> tetraquark also satisfies the tetraquark characteristics above.

- In fact, this 2<sup>nd</sup> tetraquark is more compact than the one from the spin-0 diquark.
  - $\Rightarrow$  The spin-1 diquark configuration is also important as well,
  - $\Rightarrow$  and cannot be ignored in the construction of tetraquark.
- But this 2<sup>nd</sup> type tetraquark requires another nonet to be found in PDG
  - $\Rightarrow$  do we have the candidates ?

Yes ! PDG seems to have another nonet that satisfies the same characteristics.

Heavy nonet (our selection)

- A similar **nonet** can be selected from higher resonances in  $J^P = 0^+$ ,  $f_0(1370), f_0(1500), K_0^*(1430), a_0(1450)$ 
  - GMO relation within  $\sim 4\%$ ,  $M^2[a_0(1450)] + 3M^2[f_0(1370)] \approx 4M^2[K_0^*(1425)]$
- They have the anticipated isospins,  $I = 0, \frac{1}{2}, 1$ , and
- their mass ordering, though marginal, still holds here,  $M[a_0(1450)] > M[K_0^*(1430)]$  with  $\Delta M \sim 50$  MeV,  $M[K_0^*(1430)] \gtrsim M[f_0(1370)]$ . The ‘marginal’ ordering can be explained partially by our hyperfine masses (more later!).

Name	I	J <sup>PC</sup>	Mass(MeV)	Γ(MeV)
$f_0(1370)$	0	0 <sup>++</sup>	1200-1500	200-500
$a_0(1450)$	1	0 <sup>++</sup>	1474	265
$f_0(1500)$	0	0 <sup>++</sup>	1505	109
$f_0(1710)$	0	0 <sup>++</sup>	1723	139
$f_0(2020)$	0	0 <sup>++</sup>	1992	442
$f_0(2100)$	0	0 <sup>++</sup>	2101	224
$f_0(2200)$	0	0 <sup>++</sup>	2189	238
$f_0(2330)$	0	0 <sup>++</sup>	2314	144
$K_0^*(1430)$	1/2	0 <sup>+</sup>	1425	270
$K_0^*(1950)$	1/2	0 <sup>+</sup>	1945	201

$J^{P(C)} = 0^{+(+)}$  with higher masses

Two states in  $I = 0$  may be a mixture of  $f_0(1370), f_0(1500)$

Heavy nonet could be the 2<sup>nd</sup> candidate for the tetraquark !

We have **two tetraquark types** in  $J^P = 0^+$ ,

- differed by the **spin** and **color** configuration which we denote by  $|000\rangle_{\bar{3}_c, 3_c} \Rightarrow |000\rangle$        $|011\rangle_{6_c, \bar{6}_c} \Rightarrow |011\rangle$ .
- Both form a **nonet** in flavor separately ( $8_f \oplus 1_f$ ).

PDG also has **two nonets** in  $J^P = 0^+$  with the tetraquark characteristics.

**Light nonet (Jaffe's selection)**  
The lowest-lying in  $0^+$ ,  
 $f_0(500), f_0(980), K_0^*(800), a_0(980)$

**Heavy nonet (additional selection by us)**  
From higher resonances in  $0^+$ ,  
 $f_0(1370), f_0(1500), K_0^*(1430), a_0(1450)$

The huge mass gap between the two  $\gtrsim 500$  MeV

What kind of correspondence one can make between the two sets ?

Two tetraquark types  $\Leftrightarrow$  Two nonets in PDG

A crucial observation is that

- the two tetraquarks,  $|000\rangle$ ,  $|011\rangle$ , mix through the hyperfine color-spin interaction !

$$V_{CS} \propto \sum_{i<j} \lambda_i \cdot \lambda_j \frac{J_i \cdot J_j}{m_i m_j}$$

$\lambda_i$ : Gell-Mann matrix for color,  
 $J_i$ : spin,  
 $m_i$ : constituent quark mass

- The mixing terms are nonzero,  $\langle 011 | V_{CS} | 000 \rangle \neq 0$ .
- $\langle V_{CS} \rangle$  forms a 2x2 matrix in the bases,  $|000\rangle$ ,  $|011\rangle$ ,  
 $\Rightarrow$  constituting the hyperfine mass matrix.

The upshot is that

- physical resonances, the two nonets in PDG, can be identified by the eigenstates that diagonalize the 2x2 matrix,  
 i.e., the two nonets in PDG must be superposition of  $|000\rangle$ ,  $|011\rangle$ .
- In fact, the mixing is found to be strong so it can explain the large mass gap between the two nonets.

This is our tetraquark mixing framework for the two nonets in  $J^P = 0^+$ .

 We look for its phenomenological signatures from experimental observables such as masses or decay properties !

One question

- The spin-1 diquark scenario requires additional **nonets** to be found in  $J^P = 1^{+-}, 2^{++}$  corresponding to the configurations

$$|111\rangle_{6_c, \bar{6}_c} \quad |211\rangle_{6_c, \bar{6}_c} \quad \text{※ One can prove that C-parity is negative for } J = 1, \text{ positive for } J = 2.$$

Are there such nonets in PDG ? My answer is ‘Maybe’.

- There are lots of resonances to choose but the candidate selection is not definite.

Name	I	J <sup>PC</sup>	Mass(MeV)	Γ(MeV)
h <sub>1</sub> (1170)	0	1+-	1170.0	360
b <sub>1</sub> (1235)	1	1+-	1229.5	142
h <sub>1</sub> (1380)	?	1+-	1386.0	91
h <sub>1</sub> (1595)	0	1+-	1594.0	384
K <sub>1</sub> (1270)	1/2	1+	1272.0	90
K <sub>1</sub> (1400)	1/2	1+	1403.0	172
K <sub>1</sub> (1650)	1/2	1+	1650.0	150

$J^{P(C)} = 1^{+(-)}$  resonances

Name	I	J <sup>PC</sup>	Mass(MeV)	Γ(MeV)
f <sub>2</sub> (1270)	0	2++	1275.1	185.1
a <sub>2</sub> (1320)	1	2++	1318.3	105
f <sub>2</sub> (1430)	0	2++	1430.0	?
f <sub>2</sub> '(1525)	0	2++	1525.0	73
f <sub>2</sub> (1565)	0	2++	1562.0	134
f <sub>2</sub> (1640)	0	2++	1639.0	99
a <sub>2</sub> (1700)	1	2++	1732.0	194
f <sub>2</sub> (1810)	0	2++	1815.0	197
f <sub>2</sub> (1910)	0	2++	1903.0	196
f <sub>2</sub> (1950)	0	2++	1944.0	472
f <sub>2</sub> (2010)	0	2++	2011.0	202
f <sub>2</sub> (2150)	0	2++	2157.0	152
f <sub>2</sub> (2300)	0	2++	2300.0	149
f <sub>2</sub> (2340)	0	2++	2345.0	322
K <sub>2</sub> <sup>*</sup> (1430)	1/2	2+	1425.0	98.5
K <sub>2</sub> <sup>*</sup> (1980)	1/2	2+	1973.0	373

$J^{P(C)} = 2^{+(+)}$  resonances

- Highlighted members can be selected but with some ambiguity,
  - unknown isospin of h<sub>1</sub>(1380),
  - the mass ordering, slightly violated,  $M[b_1(1235)] < M[K_1(1270)]$

## The selection is ambiguous

- maybe due to further mixings with additional tetraquarks constructed by other diquarks, and possible contamination from two-quark component with  $\ell = 1$ .
- This ambiguity does not mean that  $|111\rangle, |211\rangle$  do not exist.
  - ⇒ It simply says that the candidates do not stand out in a well-separated entity.
  - ⇒ It does not rule out our mixing framework in the  $0^+$  channel.

Testing ground of our tetraquark framework is the two nonets.

Isospin	Light nonet	Heavy nonet	
$I = 1$	$a_0(980)$	$a_0(1450)$	
$I = 1/2$	$K_0^*(800)$	$K_0^*(1430)$	
$I = 0$	$f_0(500)$	$f_0(1370)$	← close to the $8_f$ member
	$f_0(980)$	$f_0(1500)$	← close to the $1_f$ member

### Flavor mixing on isoscalars

- The  $I = 0$  members are subject to additional **flavor mixing** between  $|\mathbf{8}_f\rangle_{I=0}$ ,  $|\mathbf{1}_f\rangle_{I=0}$ , known as the OZI rule.
- Depending on how the flavor mixing is implemented, we consider three cases (Hungchong Kim et.al., PRD2018),
  - $SU(3)_f$  Symmetric Case, SSC (no flavor mixing)
  - Ideal Mixing Case, IMC
  - Realistic Case with Fitting, RCF

### According to our mixing scheme

- first we need to calculate the hyperfine masses,  $\langle V_{CS} \rangle$ , w.r.t.  $|000\rangle$ ,  $|011\rangle$  in each isospin channel.

## Color-spin interaction for four-quark system

hyperfine masses

$$V_{CS} = v_0 \sum_{i < j} \lambda_i \cdot \lambda_j \frac{J_i \cdot J_j}{m_i m_j} \quad \text{for all the pairs among 4 quarks}$$

$$= v_0 \left[ \lambda_1 \cdot \lambda_2 \frac{J_1 \cdot J_2}{m_1 m_2} + \lambda_3 \cdot \lambda_4 \frac{J_3 \cdot J_4}{m_3 m_4} + \lambda_1 \cdot \lambda_3 \frac{J_1 \cdot J_3}{m_1 m_3} + \lambda_1 \cdot \lambda_4 \frac{J_1 \cdot J_4}{m_1 m_4} + \lambda_2 \cdot \lambda_3 \frac{J_2 \cdot J_3}{m_2 m_3} + \lambda_2 \cdot \lambda_4 \frac{J_2 \cdot J_4}{m_2 m_4} \right]$$

### Master formulas for $\langle V_{CS} \rangle$

$v_0 = (-192.9 \text{ MeV})^3$  from the mass splitting,  $D_2^*(2463) - D_0^*(2318)$

$\langle J, J_{12}, J_{34}   V   J, J_{12}, J_{34} \rangle$	Corresponding formulas for one specific flavor combination, $q_1 q_2 \bar{q}^3 \bar{q}^4$
$\langle 000   V_{CS}   000 \rangle$	$2v_0 \left[ \frac{1}{m_1 m_2} + \frac{1}{m_3 m_4} \right]$ <span style="color: blue;">⇐ only diquark and antidiquark pairs contribute</span>
$\langle 011   V_{CS}   011 \rangle$	$\frac{v_0}{3} \left[ \frac{1}{m_1 m_2} + \frac{1}{m_3 m_4} + \frac{5}{m_1 m_3} + \frac{5}{m_1 m_4} + \frac{5}{m_2 m_3} + \frac{5}{m_2 m_4} \right]$ <span style="color: blue;">⇐ all the pairs contribute</span>
mixing, $\langle 000   V_{CS}   011 \rangle$	<u><math>\sqrt{\frac{3}{2}} v_0 \left[ \frac{1}{m_1 m_3} + \frac{1}{m_1 m_4} + \frac{1}{m_2 m_3} + \frac{1}{m_2 m_4} \right] \neq 0</math></u>

Ex) For the  $I = 1$  members,

Since their flavor is,  $[su][\bar{d}\bar{s}] = \frac{1}{2}(su - us)(\bar{d}\bar{s} - \bar{s}\bar{d})$ ,

we sum over all flavor combinations,

$$\langle V_{CS} \rangle = \frac{1}{4} [\langle V_{CS} \rangle_{su\bar{d}\bar{s}} + \langle V_{CS} \rangle_{su\bar{s}\bar{d}} + \langle V_{CS} \rangle_{us\bar{d}\bar{s}} + \langle V_{CS} \rangle_{us\bar{s}\bar{d}} ].$$

Hyperfine mass matrix in the  $I = 1$  channel,

- Diagonalization leads to the **physical hyperfine masses**

$$\begin{array}{c|cc} \langle V_{CS} \rangle & |000\rangle & |011\rangle \\ \hline |000\rangle & \underline{-173.9} & \underline{-222.3} \\ |011\rangle & -222.3 & \underline{-331.5} \end{array} \longrightarrow \begin{array}{c|cc} \langle V_{CS} \rangle & |0_A^{a_0}\rangle & |0_B^{a_0}\rangle \\ \hline |0_A^{a_0}\rangle & -16.8 & 0.0 \\ |0_B^{a_0}\rangle & 0.0 & -488.5 \end{array}$$

and **eigenstates** corresponding to  $a_0(980)$ ,  $a_0(1450)$

$$|0_A^{a_0}\rangle = -0.817|000\rangle + 0.577|011\rangle \Rightarrow |a_0(1450)\rangle$$

$$|0_B^{a_0}\rangle = 0.577|000\rangle + \underline{0.817|011\rangle} \Rightarrow |a_0(980)\rangle$$

This identification follows from  $\langle 0_A^{a_0} | V_{CS} | 0_A^{a_0} \rangle > \langle 0_B^{a_0} | V_{CS} | 0_B^{a_0} \rangle$

As advertised,

- $|011\rangle$  is found to be **more compact**,  $\langle 000 | V_{CS} | 000 \rangle > \langle 011 | V_{CS} | 011 \rangle$ .
  - $a_0(980)$  has **more probability** to stay in  $|011\rangle$  than in  $|000\rangle$  !!
  - ✂ The similar result was reported also by Black et.al [PRD59,074026 (1999)]. There, this mixing is used to explain why the light nonet is 'so light' without identifying the heavy nonet.
  - 👉 We emphasize that  $|011\rangle$  must be considered in tetraquark studies.
- The **strong mixing** causes **large separation** in hyperfine masses.
  - 👉 This can explain the large mass gap (500 MeV or so)
  - 👉 in addition to the lightness of the light nonet.

Similar consequences can be seen in the other isospin channels.

Including all the members,

$$\begin{aligned} |\text{Heavy nonet}\rangle &= -\alpha|000\rangle + \beta|011\rangle \\ |\text{Light nonet}\rangle &= \beta|000\rangle + \alpha|011\rangle \end{aligned}$$

(diagonal) hyperfine masses

Isospin	$\alpha$	$\beta$	Light	$\langle V_{CS} \rangle$	Heavy	$\langle V_{CS} \rangle$
$I = 1$	0.867	0.577	$a_0(980)$	-488.5	$a_0(1450)$	-16.8
$I = 1/2$	0.813	0.582	$K_0^*(800)$	-592.7	$K_0^*(1430)$	-26.9
$I = 0$ (RCF)	0.814	0.581	$f_0(500)$	-667.5	$f_0(1370)$	-29.2
$I = 0$ (RCF)	0.816	0.578	$f_0(980)$	-535.1	$f_0(1500)$	-20.1

close to the  $8_f$  member

$\sim 100$

$\sim 10$

※ Approximately,  $\alpha \approx \sqrt{2/3}$ ,  $\beta \approx \sqrt{1/3}$ .

- For the octet members, our hyperfine masses are ordered,  $\langle V_{CS} \rangle_{I=1} > \langle V_{CS} \rangle_{I=1/2} > \langle V_{CS} \rangle_{I=0}$ , the same as the masses,  $M[a_0] > M[K_0^*] > M[f_0]$ .  
 $\Rightarrow \langle V_{CS} \rangle$  is **partially responsible** for the mass ordering.
- But  $\langle V_{CS} \rangle$  splitting is much **narrower** for heavy nonet,  
 $\sim 100$  MeV for light nonet,  
 $\sim 10$  MeV or less for heavy nonet.

Our hyperfine masses explain partially the **marginal mass ordering** seen in the heavy nonet !

## Mass splitting formula

- Our first task is to test our framework in generating masses through the mass splitting formula,

$$\Delta M_H \approx \Delta \langle V_{CS} \rangle \quad V_{CS} = v_0 \sum_{i < j} \lambda_i \cdot \lambda_j \frac{J_i \cdot J_j}{m_i m_j}$$

- It says that the **mass difference** between hadrons with **the same flavor content** and **color configuration** can be approximated by their **hyperfine mass splitting** (we understand why).

✂ For example, this seems to work well for the lowest-lying baryons and mesons,  $\Delta - N, \Sigma - \Lambda, \Xi^* - \Xi, K^* - K, D^* - D, etc.$

PLB(1986)171:293, Lipkin, EPJA (2016) 52:184, PRD(2015)91:014021, H.Kim et.al.

- This splitting formula minimizes the parameter dependence so its prediction could be reliable.
- Our tetraquarks,  $|000\rangle, |011\rangle$ , have different color configurations. But the color-electric terms,  $V_{CE} = v_1 \sum_{i < j} \frac{\lambda_i \cdot \lambda_j}{m_i m_j}$ , almost cancel in the difference,  $\Delta \langle V_{CE} \rangle \approx 0$  (backup slides).

Results on mass splitting between the two nonets

$$\Delta M_H \approx \Delta \langle V_{CS} \rangle$$

For  $I = 1$

Heavy nonet	Light nonet	$\Delta M_{exp}$ (MeV)	$\Delta \langle V_{CS} \rangle$ (MeV)		
			SSC	IMC	RCF
$a_0(1450)$	$a_0(980)$	<b>494</b>	<b>471.7</b>	-	-

👉 Our mixing scheme works very well !

equal when  $m_u = m_d$

For  $I = 0, 1/2$

$M_{exp}$  is broad or not fixed well

$f_0(1500)$	$f_0(980)$	<b>515</b>	<b>541.7</b>	471.7	<u>515</u>
$f_0(1370)$	$f_0(500)$	875	<b>611.7</b>	681.7	638.3
$K_0^*(1430)$	$K_0^*(800)$	743	<b>565.8</b>	-	-

Note that the  $I = 0$  results do not depend much on how the flavor mixing is implemented. For the last two lines, precise agreement is not anticipated as the participating resonances are either very broad or their masses are poorly known.

At least, we can say from all these that the strong mixing qualitatively generates the huge gap between the two nonets.

Our second task is to test

Tetraquark signatures from the  $a_0(980)$ ,  $a_0(1450)$  decays

✧ We do not discuss the  $I = 0, 1/2$  cases due to lack of expt. data for comparison.

Tetraquark decays dominantly through the **fall-apart mechanism**.

- In this mechanism, the quark-antiquark pairs simply fall apart into two mesons.
- This decay is possible because our tetraquark have **two-meson open channel**.

↳ Namely, rearranging  $q_1 q_2 \bar{q}^3 \bar{q}^4$  into quark-antiquark pairs,  $(q_1 \bar{q}^3)(q_2 \bar{q}^4)$ , we see the nonzero component with two color singlet pairs,

$qq\bar{q}\bar{q}$  fall-apart decay

$$\begin{array}{c}
 \text{(24)} \\
 \downarrow \quad \downarrow \\
 q_1 q_2 \bar{q}^3 \bar{q}^4 \\
 \uparrow \quad \uparrow \\
 \text{(13)}
 \end{array}
 \Rightarrow [(8_c)_1 \otimes (8_c)_{24}]_{1_c} \oplus [(1_c)_{13} \otimes (1_c)_{24}]_{1_c}$$

two-meson modes

Fall-apart strength of  $a_0(980), a_0(1450)$

$$|a_0(1450)\rangle = -\alpha|000\rangle + \beta|011\rangle$$

$$|a_0(980)\rangle = \beta|000\rangle + \alpha|011\rangle \quad \alpha = 0.817, \beta = 0.577$$

- $|000\rangle, |011\rangle$  fall apart into **two mesons**, each forming a color singlet, **spin-0 state**.
- The relative sign difference leads to the coupling strengths **suppressed for  $a_0(1450)$**  but **enhanced for  $a_0(980)$** . (K.S.Kim, Hungchong Kim, EPJC2017).

Coupling strength of the fall-apart modes into two PS mesons up to an overall constant

	$a_0^+(1450)$	$a_0^+(980)$
$\bar{K}^0 K^+$	$-\frac{\alpha}{2\sqrt{3}} + \frac{\beta}{\sqrt{2}} = 0.1722$	$\frac{\beta}{2\sqrt{3}} + \frac{\alpha}{\sqrt{2}} = 0.7441$
$\eta\pi^+$	$-\frac{\alpha}{3\sqrt{2}} + \frac{\beta}{\sqrt{3}} = 0.1406$	$\frac{\beta}{3\sqrt{2}} + \frac{\alpha}{\sqrt{3}} = 0.6076$
$\eta'\pi^+$	$\frac{\alpha}{6} - \frac{\beta}{\sqrt{6}} = -0.0994$	$-\frac{\beta}{6} - \frac{\alpha}{\sqrt{6}} = -0.4296$

kinematically not allowed

- The relative enhancement factor is about **'four'** !
- Similar enhancement can be seen for the other channels (Hungchong Kim et.al., PRD2018).

Could be a clear signature for the tetraquark mixing framework.

This signature can be tested most effectively from the following ratios !

	Theory	Based on expt. analysis	
		Bugg	PDG
	2.51–2.54	2.53	2.93–3.9
$\frac{\Gamma[a_0(980) \rightarrow K \bar{K}]}{\Gamma[a_0(1450) \rightarrow K \bar{K}]}$	0.52–0.89	0.62	0.61–0.81

(backup slide)

Bugg: PRD78,074023(2008)

✧ The ratios eliminate the dependence on the overall constant.

The agreement is quite good !

- Only disagreement is in the 1<sup>st</sup> ratio in comparison with the PDG ratio but both results still point toward the enhancement and suppression of the couplings.
- Our tetraquark mixing framework seems to work for the decays.

Some comments on a **two-quark picture**

1. Is it possible to explain the two nonets ( $0^+$ ) in a **two-quark picture** ( $q\bar{q}$ ) with  $\ell = 1$  ?  
My answer is 'No'.

$$q\bar{q}: (S = 0, 1) \otimes (\ell = 1) \Rightarrow J = 0, 1, 2$$

Total $J$	Configuration	# of confs.
$J = 0$	$(S = 1, \ell = 1)$	one
$J = 1$	$(S = 0, \ell = 1), (S = 1, \ell = 1)$	two
$J = 2$	$(S = 1, \ell = 1)$	one

👉 This picture yields only one configuration in  $J^P = 0^+$ .

- Appearance of the two nonets in  $0^+$  cannot be explained by this two-quark picture.
- This gives another motivation for constructing the tetraquark framework.

2. Alternatively, one may view the heavy nonet in a  $q\bar{q}$  picture while maintaining the  $qq\bar{q}\bar{q}$  picture for the light nonet. We think this is not realistic.

- The heavy nonet, if viewed as  $q\bar{q}$  with  $\ell = 1$ , must have the configuration  $(S = 1, \text{vector nonet}) \otimes (\ell = 1) \Rightarrow J = 0$   
 $\Rightarrow$  orbital excitations of the vector mesons,  $\rho, \omega, K^*, \phi$ .

- In this picture, SO makes the heavy nonet 'heavier' than the vector nonet.
- To reproduce the expt. gap ( $\approx -50 \text{ MeV}$ ), SO must have strong dependence on isospin channels, strong enough to flip the mass ordering normally established by the quark masses.

$\Rightarrow$  This picture seems not realistic !

3. One may view the two nonets as a mixture of a two-quark ( $q\bar{q}$ ), and four-quark ( $qq\bar{q}\bar{q}$ ) ?
- But  $q\bar{q}$ ,  $qq\bar{q}\bar{q}$  do not mix under the color-spin interaction !  
 $\langle q\bar{q} | qq\bar{q}\bar{q} \rangle = 0$ ,  $\langle q\bar{q} | V_{CS} | qq\bar{q}\bar{q} \rangle = 0$ .
  - Normally this scenario requires ad hoc mixing.

## Some comments on hadronic molecules

- One may view the heavy nonet as meson-meson bound states.
- Since mesons are colorless, this picture provides shallow bound states  
⇒ Expected to be less probable to be formed in collision processes.
- Since the lowest-lying mesons form a nonet in flavor, the flavor structure of the meson-meson states would be much diverse including 27-plet  
⇒ PDG does not support this picture. (ex. no  $0^+$  resonances with  $I = 2$ .)

## Summary

- We propose a **tetraquark mixing framework** for light mesons in the  $0^+$  channel.
  - Two types of tetraquark  $|000\rangle, |011\rangle$ , have been introduced, one from the spin-0 diquark and the other from the spin-1 diquark.
  - We emphasize that  $|011\rangle$  is important in the tetraquark studies.
  - The two tetraquarks are found to mix strongly through the color-spin interaction.
  - We report that their mixture, which diagonalize the hyperfine mass, can generate the two nonets in PDG, the light and heavy nonets.

$$\begin{aligned} |\text{Heavy nonet}\rangle &= -\alpha|000\rangle + \beta|011\rangle \\ |\text{Light nonet}\rangle &= \beta|000\rangle + \alpha|011\rangle \end{aligned} \quad \text{with } \alpha \approx \sqrt{2/3}, \beta \approx \sqrt{1/3}$$

- Our mixing framework has been tested relatively well phenomenologically.
  - It reproduces the mass splitting between the two nonets.
  - Its another consequence in the decay couplings, namely coupling enhancement for the light nonet and suppression for the heavy nonet, has been tested relatively well for the decays,  $a_0(980), a_0(1450) \Rightarrow K\bar{K}, \eta\pi$ .

Our work may provide a new view on tetraquarks, especially how they are realized in the actual spectrum, i.e., through **“mixing framework”**.

Back up slides

Explanation for  $\Delta\langle V_{CE} \rangle \approx 0$

$$\begin{pmatrix} \langle 000 | V_{CE} | 000 \rangle & 0 \\ 0 & \langle 011 | V_{CE} | 011 \rangle \end{pmatrix} \Rightarrow \text{a diagonal matrix in } J = 0 \text{ channel}$$

$$\langle 000 | V_{CE} | 011 \rangle = 0 \quad \text{because } V_{CE} \text{ is blind on spin}$$

$$\langle 000 | V_{CE} | 000 \rangle \approx \langle 011 | V_{CE} | 011 \rangle$$

$$\begin{pmatrix} -23.8 & 0 \\ 0 & -24.57 \end{pmatrix} \approx -24.57 \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

- It is almost a multiple of the **identity** matrix in  $|000\rangle, |011\rangle$  basis, unchanged under diagonalization.
- $\Delta\langle V_{CE} \rangle \approx 0 \Rightarrow$  does not contribute to the mass splitting.

**Theoretical** partial widths of  $a_0 \Rightarrow K\bar{K}, \eta\pi$

- calculated by constructing effective Lagrangians but with the coupling strengths fixed from our fall-apart decays.
- The width is averaged over the mass distribution  $f(M)$  determined by the total decay width and its central mass.

$$\langle \Gamma(M_c, \Gamma_{exp}) \rangle = \frac{\int_{m_1+m_2}^{\infty} \Gamma(M) f(M) dM}{\int_{m_1+m_2}^{\infty} f(M) dM}$$

Meson	$M_c$ (MeV)	$\Gamma_{exp}$ (MeV)
$a_0(980)$	980	50-100
$a_0(1450)$	1474	265

**Expt.** partial widths of  $a_0 \Rightarrow K\bar{K}, \eta\pi$

For  $a_0(980)$ , its partial widths can be estimated relatively well from PDG,

$$\Gamma[a_0(980) \rightarrow \pi\eta] \approx 60 \text{ MeV} ,$$

$$\Gamma[a_0(980) \rightarrow K\bar{K}] \approx 10.98 \text{ MeV}$$

For  $a_0(1450)$ , two sets are available from experimental analysis.

Partial width	Bugg(MeV)	PDG(MeV)
$\Gamma[a_0(1450) \rightarrow \pi\eta]$	23.7	15.38–20.49
$\Gamma[a_0(1450) \rightarrow K\bar{K}]$	17.7	13.53–18.03
