

Observations and Theory of Three-minute Oscillations in the Solar Chromosphere

Jongchul Chae
Seoul National University

Solar Chromosphere

$n_e = 10^{12} \text{ cm}^{-3}$, $T = 6000 \text{ K}$
partially ionized

1. seen through cores of strong spectral lines
2. magnetically and energetically connecting between photosphere and corona
3. the least understood layer of the solar atmosphere

Topics of research

1. How are cool jet-like structures dynamically supported? *spicules, fibrils, surges*
2. How is energy transported? *oscillations, waves, and shocks*
3. How is magnetic energy released? *magnetic reconnection*

Physics of Three-minute Oscillations

- Three-minute oscillations reflect the
 1. **slow magnetoacoustic waves propagating upwards along magnetic field lines in the low- β plasma**
 2. **under the effect of gravity**
 3. **with the frequency close to the acoustic cutoff frequency and very long wavelengths**
- Acoustic cutoff frequency (Lamb frequency)

$$\omega_0 = \frac{\gamma g_{\parallel}}{2c_0}$$

Summary

1. Three-minute velocity oscillations prevail in the solar chromosphere
2. They are long acoustic waves with frequencies just above acoustic cutoff.
3. The peak frequency of oscillation is a direct diagnostic of the temperature and magnetic inclination of the Tm region.
4. They are driven below the photosphere either by the p-modes or by in situ magnetoconvection.
5. The waves nonlinearly develop as they propagate upwards and become shock waves in the upper atmosphere.

Prospects

Further systematic studies of three-minute oscillations will allow us to

1. infer the temperature and magnetic structure of the solar chromosphere
2. evaluate their contribution to the chromospheric heating
3. and the driving of jet-like features like spicules

Abstract

The three-minute oscillations are the most prominent dynamic activity in the chromosphere of an apparently quiescent sunspot. They are interesting to us because they may be in charge of heating the chromosphere and driving jets in the upper solar atmosphere, and they can be exploited for the inference of the atmospheric structure. In this talk, by combining our observations using the Fast Imaging Solar Spectrograph of the Goode Solar Telescope, and our theoretical works that are mostly analytical, I will present several important results on this phenomenon. First, the three-minute oscillations represent long-wavelength slow magneto-acoustic waves upwardly-propagating in a gravitationally stratified medium. They are dispersive waves and have very low group velocities, and high phase speeds. Second, the frequency the oscillations is determined by the temperature and magnetic inclination of the temperature minimum region.

31

Abstract (continued)

- Third, they can be generated by impulsive disturbances somewhere in or below the atmosphere. The most dominant source may be magneto-convection beneath the photosphere. Fourth, the three-minute oscillations develop into shock waves as they propagate upward. Since they form shock waves, however, at larger heights than short wavelength waves do, they can play a potential role in the heating of plasma in the upper atmosphere. The nonlinearity can be measured by the growth of the second order harmonic component. Finally, the longer-period shock waves can be produced by the successive merging of three-minute shocks. These shock waves seem to be in charge of the driving of plasma jets in the chromosphere.
